Abstract

Employee contextual performance is a crucial determinant of organizational effectiveness, growth, and performance. Therefore, this research focuses on employees' contextual performance issues seen from the perspective of boundary-spanning leaders (BSL), creativity, and proactive work behavior (PWB). The aim is to reveal the effect of BSL, creativity, and PWB on employees' contextual performance and find new models of the role of creativity and PWB in mediating the effect of BSL on employees' contextual performance. The research involved 420 employees from companies in the finance, trade, services, and investment industry sectors in Indonesia. A Likert scale questionnaire designed in Google Forms was used to conduct a survey via the WhatsApp application. Data analysis using structural equation modelling (SEM) shows that BSL, creativity, and PWB significantly direct affect employees' contextual performance; BSL and creativity significantly direct affect employees' PWB; and BSL significantly indirectly affect employees' contextual performance mediated by creativity and PWB. Accordingly, this study proves a new empirical model regarding the effect of BSL on employee contextual performance mediated by creativity and PWB. Based on these findings, this study suggests that researchers and practitioners utilize the empirical model from this study as a strategy to improve employee contextual performance through BSL with a mediation mechanism of creativity and PWB in the future.

Keywords: boundary-spanning leader, creativity, proactive work behavior, contextual performance.

Introduction

Employee performance has always been the center of attention of researchers and practitioners for several very rational strategic reasons. First, empirically proven employee performance has an effect on organizational effectiveness (Tahsildari & Shahnaei, 2015). Second, it makes a positive contribution to organizational growth (Vosloban, 2012). Finally, employee performance can also improve organizational performance (Fahmi et al., 2019). Conceptually, performance is a set of work-related actions that are specifically designed to achieve organizational goals (Colquitt et al., 2019), including contextual performance, namely employee actions that make a positive contribution to organizational effectiveness by providing conducive working conditions so that tasks are formal employee tasks can be completed properly (Aguinis, 2018).

Contextual performance reflects actions that are not directly related to the formal tasks of the company but make a positive contribution to the organization, social relationship, and employees' psychological condition, such as employee work behavior that goes beyond organizational expectations (Chin & Yusoff, 2017) and voluntary actions that go beyond job descriptions (Bilal et al., 2021; Dongrey & Rokade, 2022). Contextual performance includes two distinct aspects: job dedication and interpersonal facilitation (Sante et al., 2021). Job dedication is a behavior that reflects discipline, effort, and

enthusiasm at work, such as overtime and taking on additional task roles. Meanwhile, interpersonal facilitation demonstrates the role of praising, entertaining, and supporting colleagues in the workplace, such as being friendly and demonstrating qualities that meet the expectations of the social environment (van Scotter & Motowidlo, 1996). Contextual performance as a response to employee behavior towards equality can facilitate the implementation of diversity-related human resource programs and practices. It can spread positive employee views on workforce diversity managerial practices and supportive behavior towards the organization, which has positive implications for healthier and cohesive work lives (Dongrey & Castle, 2022). In line with some views above, Aguinis (2018) mentions contextual performance indicators: persisting with enthusiasm and exerting extra effort as necessary to complete one's task activities successfully; volunteering to carry out task activities that are not formally part of the job; helping and cooperating with others; following organizational rules and procedures; and endorsing, supporting, and defending organizational objectives.

In practice, many employees are unable to display such behavior. For example, many employees are less enthusiastic at work, do not fully follow the work rules and procedures that apply in the company, and are not optimal in supporting the achievement of company goals. Some of them are also not moved to help colleagues who are having trouble completing their work and are also not interested in taking on additional

roles without compensation. As a result, they fail to complete their assignments with the best quality. In Indonesia, this phenomenon also occurs in companies in the finance, trade, services, and investment industry sector. Empirically, the phenomenon (employee performance) is influenced by BSL (Xue & Woo, 2022), creativity (Suryanto et al., 2021), and PWB (Ying et al., 2022). However, other studies show inconsistent results. For example, a recent study by Farida et al. (2022) and Dita et al. (2022) indicated that leadership has no significant effect on performance. Further, the research results by Anjaningruma and Rudamaga (2019) prove that creativity does not affect performance. Moreover, Du et al. (2021) prove that creativity influences leadership. It shows research gaps that require scientific clarification through research. Therefore, this study investigates the contextual performance problems of employees from the perspective of BSL, creativity, and PWB and seeks to find mediation mechanisms for the influence of BSL on employee contextual performance through creativity and PWB.

Literature Review and Hypothesis Development

BSL and Contextual Performance

BSL is the capability of setting direction, alignment, and commitment across borders to realize the vision or goals of the organization (Ernst & Chrobot-Mason, 2010; Ernst & Yip, 2009). Thus, BSL relates to the actions of leaders or managers in interacting and collaborating with other parties in the external environment by crossing organizational (team) boundaries in order to protect internal interests from external uncertainty and strengthen internal organizational solidarity (Benoliel & Somech, 2015; Kwon & Woo, 2019). BSL also refers to leadership behavior that contributes to the achievement of organizational goals through empowering subordinates by exploring and obtaining the necessary resources and information through communication with outsiders (externals) that are disseminated to subordinates (Glaser et al., 2015; Takanashi & Lee, 2019). According to Yip et al. (2016), effective organizational leadership occurs when groups within the organization interact and collaborate intensively with outsiders across boundaries to achieve better results.

Researchers have presented six practices of BSL: buffering, reflecting, connecting, mobilizing, weaving, and transforming. They then summarized it into three strategies, each covering two practices. The first strategy to manage boundaries includes buffering and reflecting. The second strategy to forge common ground comprises connecting and mobilizing. The third strategy to discover new frontiers consists of weaving and transforming (Ernst & Chrobot-Mason, 2011; Cross et al., 2013). Besides, BSL is classified into several categories, namely cognitive, relationship, and professional skills, as well as strategies for boundary management, creation of shared boundaries, and discovery of new boundaries (Nazarzadeh Zare & Ghoraishi Khorasgani, 2022). However, Yip et al. (2016) suggest the three priority dimensions of BSL: collaboration across functions, empowering employees, and developing cross-organizational learning capabilities. Previous studies claim the direct effect of BSL on subordinates' job performance, arguing that job performance can be improved by making more objective decisions as information and knowledge can be readily acquired and utilized from outside the boundary (Ancona & Caldwell, 1992a; Ancona & Caldwell, 1992b). Gull et al. (2014) and Xue and Woo (2022) also demonstrated that BSL affects

job performance. Nevertheless, specific research regarding the effect of BSL on contextual performance is challenging to find, so very interesting to be investigated. Accordingly, it can promote the first hypothesis (H):

H1: BSL has a direct effect on employees' contextual performance.

Creativity and Contextual Performance

Recently, creativity has become increasingly popular because of its position as a pillar of competition, from the micro (individual) to the macro (global) levels (Widodo & Gunawan, 2021). Empirically, employee creativity is proven to affect business development and profitability (Chen et al., 2021). It happens because increased employee creativity can encourage enhanced production (Arokiasamy et al., 2022). Furthermore, in the educational context, teacher creativity significantly affects students' creativity (Machali et al., 2021). It shows that creativity is very crucial for the lives of individuals and organizations.

Scholars interpret creativity in various ways, although the essence is relatively the same. Carter (2014), for example, views creativity as the ability to construct new concepts or generate original ideas. Kaufman et al. (2019) state that creativity generates novelty ideas or products. Then, Corazza and Lubart (2021) describe creativity as the actual manifestation of knowledge in producing novelty or original evidence. Miao and Cao (2019) also believe creativity is the ability to generate new ideas and ways, including using new technologies and procedures to achieve goals. For Sudjarwo et al. (2019), creativity reflects an imaginative and spontaneous idea or mindset that contains new creations and discoveries. In the context of teaching, Widodo and Gunawan (2021) highlighted that creativity is the ability to reconstruct new or original ideas that are relevant to the materials, approaches, methods, techniques, and styles used in the learning process. From some of these traders, in essence, creativity produces something new, whether it is in the form of ideas, ideas, concepts, services, or products.

Besant and Tidd (2018) mention kinds of creativity, including pattern recognition, divergent and convergent thinking, associations, and incremental and radical. Meanwhile, according to Huang et al. (2020), creativity is a multidimensional construct consisting of cognitive, affective, and psychomotor dimensions. Scholars identified several indicators for measured creativity, namely fluency, flexibility, originality, elaboration, and redefinition (Guliford, 190; Widodo & Gunawan, 2021). Researchers indicated that creativity significantly affects contextual performance (Chandrasekara & Kappagoda, 2019; Kaveski & Beuren, 2020; Suryanto et al., 2021). Therefore, it can formulate the second hypothesis:

H2: Creativity has a direct effect on employees' contextual performance.

PWB and Contextual Performance

Proactive behavior is an employee's action in creating or controlling a situation by taking the initiative or predicting events (Grant et al., 2008). Proactive behavior also refers to initiatives and work behaviors that start with oneself and then are adopted by other employees to overcome various difficulties in achieving goals (Hou & Huang, 2021). Therefore,

proactive work behavior includes anticipatory actions involving problem prevention, seizing opportunities, and independent efforts to improve and change work situations and the future (van Dick et al., 2007; Parker et al., 2010). Despite empirical facts showing that proactive behavior can increase career success and employee performance (Fuller & Marler, 2009; Thomas et al., 2010; Tornau & Frese, 2015), some experts believe that leaders and peers do not always appreciate proactive behavior because it can sometimes lead to negative outcomes (Pingel et al., 2019; Cangiano et al., 2020; Zhang et al., 2020). It occurs because proactive behavior can result in changing roles at work, contrary to the norms that apply in the organization and not in accordance with applicable work procedures (Fay & Frese, 2001; Grant & Ashford, 2008). This controversy requires scientific justification, so the study of PWB always has its charm. The PWB construct consists of four components: taking charge, voice, problem prevention, and individual innovation (Parker & Collins, 2010). Taking charge is an activity on its initiative voluntarily and oriented toward change and improvement (Morrison & Phelps, 1999). Voice refers to innovative suggestions, sharing ideas or thoughts with colleagues to create better conditions (Lepine & van Dyne, 2001). Problem prevention involves avoiding problems that could potentially interfere with work or oneself (Frese & Fay, 2001). Finally, individual innovation refers to creating and implementing new ideas in the workplace (Scott & Bruce, 1994). Ying et al. (2022) show that PWB is related to job performance. Thus, it can follow the third hypothesis:

H3: PWB has a direct effect on employees' contextual performance.

BSL and Creativity

BSL not only affects contextual performance but also has indications related to creativity. The study by Kim et al. (2022) shows that leader boundary-spanning behavior affects creative behavior. It means that the massive and effective implementation of BSL by leaders or managers can increase employee creative behavior. In more detail, for example, company leaders or managers who collaborate across functions and develop cross-organizational learning capabilities intensely will stimulate employees to work more fluently and flexibly as a team. They may also elaborate and redefine work problems that cannot be solved optimally. Hence, it can propose the fourth hypothesis:

H4: BSL has a direct effect on employees' creativity.

BSL and PWB

BSL also has the potential to affect PWB. An investigation by Meng et al. (2017) indicates that leader boundary-spanning behavior influences team innovation. In practice, team innovation is the accumulation of individual innovations as an indicator of PWB. Hence, BSL has the opportunity to make a positive contribution to PWB. For instance, leaders or managers who are actively empowering employees at all levels can encourage employees to be able to prevent problems from arising in the workplace and increase individual innovation among employees, such as creating and implementing new ideas in the workplace. Therefore, it can formulate the fifth hypothesis:

H5: BSL has a direct effect on employees' PWB.

Materials and Methods

Research Approach and Design

This study uses a quantitative approach with a causal design, namely the effect of exogenous variables on the mediator and endogenous variables. As an exogenous variable is BSL, while the endogenous variables are creativity, PWB, and contextual performance. However, creativity and PWB are also mediator variables besides being endogenous variables.

Sample and Sampling Technique

This research sample is 420 participants. They are companies' employees of finance, trade, services, and investment industry across six provinces in Java Island as Indonesian industry and business centers, namely Jakarta, West Java, Banten, Central Java, Yogyakarta, and East Java. They were selected by accidental sampling technique based on their availability and willingness to fill out a complete questionnaire without receiving any compensation during the study (Widodo, 2019). Profiles of them, as presented in Table 1, the majority of gender: female (54.76%), ages: 20 – 25 years (55.00%), education: senior high school (52.62%), marital status: unmarried status (63.81%), job experience: < 5 years (60.95%), Position: staff (95.24%), and employment status: contract (52.14%).

Profile	Amount	Percentage

Table 1. Profile of the Research Participants

Instrument

This research was conducted through a survey using a Likert scale model questionnaire consisting of five alternative answers, from strongly disagree/never (score = 1) to strongly agree/always (score = 5). The survey was conducted online using Google Forms, which can be shared via the WhatsApp application. The questionnaire as an instrument was constructed by researchers based on the theoretical dimensions or indicators of the experts. For BSL, indicators were collaboration across functions (CAF), empowering employees at all levels (EEAL), and developing cross-organizational learning capabilities (DCLC) (Yip et al., 2016). Creativity indicators: fluency (Flue), flexibility (Flex), originality (Orig), elaboration (Elab), and redefinition (Rede) (Guilford, 1950; Widodo & Gunawan, 2021). PWB indicators: taking charge (TC), voice (Voi), problem prevention (PP), and individual innovation (InIn) (Parker & Collins, 2010). Finally, indicators of contextual performance: persisting with enthusiasm and exerting extra effort as necessary to complete one's task activities successfully (CTS); volunteering to carry out task activities that are not formally part of the job (VTC); helping and cooperating with others (HCO); following organizational rules and procedures (FORP); and endorsing, supporting, and defending organizational objectives (ESD). The item number of BSL: nine, creativity: ten, PWB: 12, and contextual performance: ten, with a corrected item-total correlation coefficient of BSL = .568 to .745, creativity = .506 to .725, PWB = .380 to .839, and contextual performance = .403 to .774, and alpha coefficient of BSL = .890, creativity = .886, PWB = .907, and contextual performance = .877. The corrected item-total correlation coefficients of all items are > .361, and the alpha coefficient of a construct is .70, which indicates a valid and reliable research instrument (Widodo, 2019).

Data Analysis

A structural equation model (SEM) is used to analyze research data. As a complement and support, it also used descriptive and correlational analysis. In addition, to determine the significance of the indirect (mediation) effect, the Sobel test (Z) was used (Abu-Bader & Jones, 2021). LisRel version 8.80 was used for SEM analysis, while SPSS version 22 was used for descriptive and correlational analysis.

Result

Descriptive and Correlation Analysis

As shown in Table 2, The descriptive analysis result indicates the mean value indicators of BSL, from the lowest to the highest, are DCLC = 10.55, EEAL = 11.38, and CAF = 12.31. Creativity: Rede = 7.85, Flex = 8.22, Orig = 8.26, Elab = 8.44, and Flue = 8.45. PWB: InIn = 11.08, PP = 11.10, Voi = 11.20, and TC = 11.43. Finally, contextual performance: CTV = 7.10, HCO = 7.76, CTS = 7.77, ESD = 8.44, and FORP = 8.79. Meanwhile, the standard deviation (std. dev) values of the BSL indicators, from the lowest to the highest, are: CAF = 2.467, EEAL = 2.614, and DCLC = 3.120. Creativity: Elab = 1.277, Flue = 1.384, Flex = 1.393, Orig = 1.397, and Rede = 1.456. PWB: Voi = 2.288, PP = 2.618, InIn = 2.619, and TC = 2.356. The contextual performance: FORP = 1.355, ESD = 1.460, CTS = 1.548, HCO = 1.728, and CTV = 2.040. Generally, the average value is greater than the standard deviation value. It indicates a good representation of the overall data. In addition, overall, the correlation between indicators is significant at $p < 0.01$. It shows a reciprocal relationship between indicators.

Table 2. Descriptive Statistics and Correlation Analysis

** $p < .01$

Confirmatory Factor Analysis (CFA)

The CFA results summarized in Table 3 show the factor loading values of all indicators ≥ 0.3 , indicating validity (Costello et al., 2005). It means that all indicators can measure

constructs (variables). Further, the CR and α values for all variables are $> .70$, and the VE value is $> .50$, indicating good reliability and acceptable convergence (van Griethuijsen et al., 2015; Hair et al., 2018).

Construct	Indicators	Factor Loading	CR	VE	α
BSL (X)	CAF	.70	.847	.651	.890
	EEAL	.86			
	DCLC	.85			
Creativity (Y1)	Flue	.70	.858	.550	.886

Table 3. Results of the Measurement Model

Goodness of Fit (GOF)

The results of the GOF test show that from the eleven measurements of the criterion, eight good fits: GFI (.89 $\geq$.09), NFI (.94 $>$.90), NNFI (.95 $\geq$.90), AGFI (.90 $\geq$.90), CFI (.96 $\geq$.90), RFI (.93 $\geq$.90), Normed chi-square (1.27 $<$ 3), PNFI (.79, between 0 – 1), one is marginal fit: RMSEA (.085 $\leq$.08), and two are poor fit: Chi-Square (455.93 $>$ 124.34), Sig. Probability (.000 $<$.05). Specifically for the chi-square test, Hair et al. (2018) highlight that it is susceptible to large sample sizes, more than 200. Meanwhile, this study participant (sample) is 420. Therefore, it can be understood if the chi-square result test of this study is poor (it does not meet the criteria). However, this condition does not interfere with the fit of the empirical model with the theoretical model because of eight good fit criteria and one marginal fit criterion.

Hypothesis Testing

The hypothesis testing results visualized in Figure 1 and Figure 2 and summarized in Table 4 show that all hypotheses

are supported (t value $>$ t table at $\alpha = 0.01$). In detail, BSL significantly affects employees' contextual performance ($\gamma = .23$, $p < .01$), creativity significantly affects employees' contextual performance ($\beta = .19$, $p < .01$), PWB significantly affects employees' contextual performance ($\beta = .49$, $p < .01$), and BSL significantly affects employees' creativity ($\gamma = .44$, $p < .01$), BSL significantly affects employees' PWB ($\gamma = .46$, $p < .01$). The lowest path coefficient (factor loading) value is the effect of creativity on contextual performance, while the highest is the effect of PWB on contextual performance. The path coefficient value indicates the strength of influence (Widodo, 2019). The PWB path coefficient value on contextual performance is the highest. It shows that PWB has a stronger influence on employee contextual performance than BSL and creativity. All path coefficient values are positive, indicating that the existence of BSL, creativity, and PWB can improve employee contextual performance. Thus, BSL, creativity, and PWB will have consequences for increasing employees' contextual performance. In addition, BSL improvements will also make a positive contribution to enhancing employees' creativity and PWB.

Chi-Square=455.93, df=114, P-value=0.00000, RMSEA=0.085

Figure 1. Standardized Structural Model

Chi-Square=455.93, df=114, P-value=0.00000, RMSEA=0.085

Figure 2. T-Value Structural Model

Hypothesis	FactorLoading (γ/β)	T Value	Decision
H1: BSL (X) on contextual performance (Y3)	.23**	3.61	Supported
H2: Creativity (Y1) on contextual performance (Y3)	.19**	3.44	Supported
H3: PWB (Y2) on contextual performance (Y3)	.49**	7.41	Supported
H4: BSL (X) on creativity (Y1)	.44**	7.54	Supported
H5: BSL (X) on PWB (Y2)	.46**	8.60	Supported

Table 4. Hypothesis Testing Results

** $p < .01$

Table 5 presents the significant role of creativity and PWB in mediating the influence of BSL on employee contextual performance. It means that BSL indirectly has a significant effect on employees' contextual performance mediated by creativity ($\beta = .09$, $p < .01$) and PWB ($\beta = .22$, $p < .01$).

However, PWB has a better mediating role than creativity. It indicates that PWB has a stronger mediating effect on contextual performance than creativity, so its presence needs more attention than creativity.

Mediation Effect	Factor loading (β)	Z Value	Decision
BSL (X) on contextual performance (Y3) mediated by creativity (Y1)	.09**	6.16	Supported
BSL (X) on contextual performance (Y3) mediated by PWB (Y2)	.22**	7.29	Supported

Table 5. Mediation Effect Results

** $p < .01$

BSL significantly affects employees' contextual performance ($\gamma = .23$, $p < .01$), creativity significantly affects employees' contextual performance ($\gamma = .19$, $p < .01$), PWB significantly affects employees' contextual performance ($\gamma = .49$, $p < .01$), and BSL significantly affects employees' creativity ($b = .44$, $p < .01$), BSL significantly affects employees' PWB ($b = .46$, $p < .01$).

Discussion

This study found that BSL, creativity, and PWB have a significant direct effect on employees' contextual performance; BSL and creativity have a significant direct effect on employees' PWB, and BSL has a significant indirect effect on employees' contextual performance mediated by creativity and

PWB. Therefore, this study proves a new empirical model regarding the effect of BSL on employee contextual performance mediated by creativity and PWB. Overall, these findings align with and support previous research used to develop hypotheses. In detail, BSL has a significant direct effect on employees' contextual performance with factor loading (γ) = .23 ($p < .01$). This empirical fact shows that BSL is a crucial antecedent for employee contextual performance. This means that improving the implementation of BSL among company leaders at various levels can encourage an increase in employee contextual performance. For example, improving employee empowerment at all levels can encourage employees to work enthusiastically and exert extra effort to complete tasks successfully. This is in line with the study by Gull et al. (2014) and Xue and Woo (2022) that BSL affects job performance.

This study also shows that creativity has a significant effect on employee contextual performance with factor loading (β) = .19 ($p < .01$). This finding indicates that creativity is an important determinant of employees' contextual performance. This means that improving employee creativity can stimulate an increase in contextual performance. As an illustration, fluency, and flexibility can make it easier for employees to follow organizational rules and procedures. Likewise, elaboration and redefinition can encourage employees to work enthusiastically and with dedication in completing tasks so that they can help the company realize its goals. It is in line with and confirms the research results of Chandrasekara and Kappagoda (2019) and Kaveski and Beuren (2020), which prove that creativity has a significant effect on employee contextual performance.

This study specifically also reveals the empirical fact that PWB has a significant effect on employees' contextual performance with factor loading (β) = .49 ($p < .01$). In fact, its influence is stronger than BSL and creativity. This finding suggests that PWB is a key factor that greatly determines employee contextual performance. With such a strategic position, when employee PWB is improved, it will be followed by an increase in contextual performance. For example, creating and implementing new ideas in the workplace can help a company realize its goals. In addition, problem prevention measures so as not to interfere with work can help employees support, maintain and realize company goals. It shows that PWB can be relied upon to improve employee contextual performance. This empirical fact is consistent with the study of Ying et al. (2022), which proves that PWB can improve performance.

In addition, this study also proves that BSL influences creativity and PWB with factor loading (γ) = .44 and .46 ($p < .01$). It indicates that BSL is crucial for employee creativity and PWB. Thus, improving BSL practices in companies at various levels of management can support increased employee creativity and PWB. For example, collaboration across functions and developing cross-organizational learning capabilities carried out intensively by leaders/managers can help employees work more smoothly and easily as a team. Further, leaders or managers actively empowering employees can encourage employees to be able to prevent problems and make them easily create and implement new ideas. This finding is similar to the research results of Kim et al. (2022), which proves that leader boundary-spanning behavior affects creative behavior, and the study by Meng et al. (2017) indicates that leader boundary-spanning behavior influences individual innovation as an indicator of PWB.

Finally, this study also conclusively confirms that BSL has a

significant indirect effect on employee contextual performance mediated by creativity and PWB with factor loading (β) = .09 and .22 ($p < .01$). These findings prove a new empirical model regarding the effect of BSL on employees' contextual performance mediated by creativity and PWB. It shows the strategic role of creativity and PWB in mediating the influence of BSL on employees' contextual performance. However, PWB has a better mediation role than creativity. In fact, PWB directly also has a stronger influence compared to BSL and creativity. It indicates the vitality of PWB for the contextual performance of employees, so that existence needs to be given more attention and development in the future.

Conclusion

Employee contextual performance is a crucial determinant for organizational effectiveness, growth, and performance, including companies in the finance, trade, services, and investment industry sectors in Indonesia. This study found that BSL, creativity, and PWB significantly direct affect employees' contextual performance; BSL and creativity significantly direct affect employees' PWB; and BSL significantly indirectly affect employees' contextual performance mediated by creativity and PWB. Accordingly, this study proves a new empirical model regarding the effect of BSL on employees' contextual performance mediated by creativity and PWB. Based on these findings, this study suggests that researchers and practitioners utilize the empirical model from this study as a strategy to improve employee contextual performance through BSL with a mediation mechanism of creativity and PWB in the future.
